APPENDIX: QUESTIONNAIRE AND DETAILED FINDINGS ..... 20

Do I need to worry about STDs and HIV - and how do I protect myself? Which method of birth control is right for me? Will I get pregnant? Are children in my future? What should I discuss with my doctor and my partner? These are important questions that almost every woman will face at some point in her life. And how she answers them can make a big difference for her health and well-being.

Consider these facts: At least one in four Americans will contract an STD, including HIV, in their lifetime. ${ }^{1}$ Many STDs have no symptoms, but these infections - if left untreated - can have long-term health consequences for women, including infertility, pregnancy complications, chronic diseases such as cancer, and even death. Almost half of the 6.3 million pregnancies in the U.S. each year are unintended, and half of those occur among women who say they were using a regular method of contraception. ${ }^{2}$

Sexual health issues are a critical part of women's health. Yet, many women don't talk about these topics with anyone - including friends, sexual partners, and health care providers - leaving important conversations neglected. Women's knowledge about sexual health can be incomplete, and their attitudes are sometimes contradictory.

Stigma. Silence. Information gaps. Misperceptions. Because they all put women's health at risk, the Henry J. Kaiser Family Foundation and SELF magazine teamed up to provide women with the facts and resources they need to protect themselves. To better understand what women are thinking - and doing - about their sexual health, the Foundation and $S E L F^{\circ}$ conducted a nationally representative survey of 800 women ages 18-49 about their awareness and attitudes about these issues, including whether and how they communicate with their partners and health care providers.

The survey reveals the areas in which women need the most information and support, and examines their sexual health concerns through key life stages - particularly by
age and relationship status. The results of the survey, which are outlined below, also appear in the July 2003 issue of SELF magazine along with a series of stories and a resource guide on sexual health - Take Charge of Your Sexual Health.

## KEY FINDINGS: STDS AND HIV

STIGMA AND SILENCE

More than nine in 10 women agree that people often feel more embarrassed about having an STD than about other health issues, and that feeling tends to translate into silence. In fact, two-thirds of women agree that STDs are not something people talk about - even with close friends. Only half report having discussed HIV/AIDS or other STDs with their health care providers, far fewer than the number of women who discuss most other sexual health issues. The communication gaps are even wider with sexual partners: Only half of women have talked about HIV testing and only two in five have discussed testing for other STDs.

Women cite similar reasons for not talking about these issues with partners or providers. Top reasons include embarrassment, concern over how their provider or partner might react, and difficulty in knowing how to bring up certain subjects. Lack of information about sexual health issues is also a reason women give to explain why they sometimes avoid these discussions.

## kNOWLEDGE GAPS

Almost all women know that STDs can be spread through sexual intercourse and that many people with STDs may not have any symptoms. Still, one in three women does not realize that you can be infected with some STDs without having intercourse, and 10 percent are not aware that STDs can be spread through oral sex. Almost one in six
women does not know that STDs can be spread even when symptoms are not present. When it comes to the consequences of STDs, the majority of women know that they can cause fertility problems as well as pregnancy complications, but two in five are not aware that STDs can cause some kinds of cancers.

CONFUSION ABOUT TESTING

Nearly two-thirds of women report having been tested for HIV, and more than half say they have been tested for other STDs. However, some women may assume they were tested - even when they may not have been. At least one in six women who report having been tested believed that it was a routine part of their gynecological exam (even though HIV tests require explicit consent and providers typically seek consent when testing for other STDs). There is also some confusion about what a Pap smear does and does not do. While more than four in five women know that a Pap primarily screens for abnormal cells that can indicate pre-cancer or cancer, two in five believe it is a test for STDs and nearly one in 10 believe it is a test for HIV or pregnancy.

LIMITED PERSONAL CONCERN

Nine out of 10 women cite STDs and HIV/AIDS as sexual health concerns, but far fewer say they are personally concerned about these issues. Fewer than half say they are personally concerned about HIV/AIDS or other SIDs, compared with the roughly four in five who express personal concern about breast and reproductive cancers and heart disease. Women's attitudes about who they believe is more likely to be at risk for STDs may help explain this dichotomy, since nearly half of women say that STDs are not a problem if a person is "responsible."

## KEY FINDINGS: CONTRACEPTION

CONDOM CONTRADICTIONS

Most women report that they have suggested using a condom with a partner. Still, more than a third of sexually active women admit that they have been in a situation when they intended to use a condom - but did not. A third have also had a partner try to talk them out of using a condom.

Some women are concerned that using a condom might convey implicit messages about their partner's - or their own - sexual history. While most women believe that a person who carries a condom looks responsible, half still feel that it also looks like that person has a lot of sexual partners. More than two in five women also report that it is embarrassing to buy condoms, even though seven in 10 women say they have done so.

## PILL MISPERCEPTIONS

Oral contraceptives remain the most common method of reversible birth control among adult women, ${ }^{3}$ likely reflecting women's confidence in the pill's effectiveness at preventing pregnancy. Yet, almost ten percent of women incorrectly think that bith control pills also provide at least some protection from HIV/AIDS and other STDs.

In the past five years, more women have learned about emergency contraceptive (EC) pills, which can prevent pregnancy after sex. Yet, only about two-thirds of women say they are aware that there is something a woman can do in the event of contraceptive failure or unprotected sex, and barely one in 20 have ever used EC.

## SURVEY SUMMARY

I. SEXUAL HEALTH CONCERNS

The majority of women equate STDs and HIV/AIDS with sexual health. About seven in 10 consider sexual function, reproductive cancers - such as uterine, cervical, or ovarian cancer - and fertility to be sexual health issues. In addition, more than half classify breast cancer and menstruation in this category (See Chart 1). How women define sexual health does not change significantly throughout their reproductive lives, except when it comes to fertility: Younger women are more likely to consider fertility a sexual health issue than older women.

When it comes to their own health, more women are focused on breast and reproductive cancers than on HIV/AIDS or other STDs. More than four in five say they
are concerned about breast cancer, and more than three in four say they worry about reproductive cancers as well as heart disease. In contrast, less than half of women say they are personally concerned about HIV/AIDS and other STDs and a third worry about fertility (See Chart 2). Younger women and those who are single tend to say they worry about HIV/AIDS, other STDs, and fertility somewhat more than their older or married/cohabiting counterparts.

Interestingly, the degree to which a woman feels personal concern may not necessarily reflect the likelihood that she will experience a particular sexual health problem. For example, the top two rated health concerns - breast and reproductive cancers - together account for roughly 290,000 new diseases annually, ${ }^{4}$ compared with the estimated 15 million new STD and HIV infections that occur each year. ${ }^{5}$

## CHART 1

DEFINING SEXUAL HEALTH
Percentage of women who consider the following to be sexual health issues

## CHART 2

II. THE SILENCE AROUND SEXUAL HEALTH ISSUES

Despite their prevalence, STDs often invoke feelings of judgment and shame - leading many women to stay silent about them. About half of the women surveyed believe that STDs are not a problem if you are "responsible," and more than nine in 10 women say that people feel more embarrassed about having an STD than they do about other health issues. Two-thirds agree that STDs are something that people don't even talk about with close friends (See Chart 3). Single women tend to be somewhat less likely to agree with this statement than those who are married or living with someone.

CONVERSATIONS WITH HEALTH CARE PROVIDERS
About four in five women report that they routinely discuss breast self exams, birth control, and weight and physical activity with their health care providers. Almost three-quarters say they have talked about their sexual history or mammograms, with the latter conversations increasing significantly as a woman ages. In contrast, about half have discussed HIV/AIDS or other STDs, with younger women and those who are single more likely to have done so. Overall, two in five women have discussed fertility (See Chart 4).

CHART 3
STIGMA SURROUNDING SEXUAL HEALTH ISSUES
Percentage of women who agree with the following

CHART 4
TALKING TO PROVIDERS
Percentage of women who say they have discussed the following with a health care provider

For some women, talking with a provider about sexual health can be difficult. When asked about the reasons they had problems discussing these topics, one in five cites embarrassment or fear of judgment on the part of the provider, and one in six says they didn't know what questions to ask. Fourteen percent also say there wasn't enough time or they simply didn't think their provider needed to know.

How much women are saying to their health care providers can vary significantly, depending on whether or not they are single or married/cohabiting. On average, single women are more likely to be discussing sexual health issues with their providers, reporting conversations about their sexual history, HIV/AIDS, and other STDs more than their counterparts who are married or living with someone. Single women are also more likely to say that a health care provider has advised them about STD testing.

Embarrassment or shame may mean that at least a few women haven't been completely honest at the doctor's office. Roughly one in six reports keeping information about some aspect of their sexual health from their provider, including information about their sexual history, their birth control use, whether they have ever had an abortion, or their history with STDs (See Chart 5).

At the same time, single women are also more likely to say they have had problems talking about these issues because they thought their provider might be judging them. They are also more likely to say they have not been completely honest about their sexual history.

## CHART 5

HONESTY IN THE EXAM ROOM

COMMUNICATING WITH PARTNERS
Women are talking more with their partners about sexual health issues, at least compared to the discussions they are having with their health care providers. Yet, in both cases, HIV/AIDS and STDs remain the least talked-about subjects. There are also significant differences in what - and how - women talk about sexual health in their relationships when they are married/living together compared to when they are single. Married/cohabiting women are more likely to say they have discussed pregnancy and having children - as well as different birth control options. Single women are more likely to have discussed their sexual histories, using condoms, and getting tested for HIV and other STDs (See Chart 6).

When it comes to initiating sexual health conversations or dealing with birth control, sexually active single women are more likely to say that the talk - and the actions - fall to them. To be fair, these women report that between a third to half of their male partners share the responsibility for bringing up sexual histories, condom use, and STD/HIV testing - and making sure birth control is used. Yet, a sizeable number say that they - not their partners - are the initiators. And, when it comes to who pays for contraception, women are more likely to say they foot the bill than say that the responsibility is a shared one (See Chart 7). In contrast, women who are married or living as married are more likely to say it was no longer relevant to their lives to discuss who plays each role in their relationship or reported a more equal split of responsibility.

## CHART 6

KEEPING LINES OF COMMUNICATION OPEN
Percentage of sexually active women in relationships who have talked about each of the following with their partner

## CHART 7

SEXUAL HEALTH COMMUNICATORS
Percentage of sexually active single women who say the role of each of the following is usually

Although many women report that they personally talk to their partners about sexual health issues, they also assume that women may keep some information from their partners. Nine in 10 say they believe women keep information from their partners about their sexual history at least "sometimes," and more than four in five say women at least "sometimes" withhold information about their history with STDs. More than two-thirds also say they think the same is true about information about birth control use.

The top reasons women give for why women may not talk to their partners are a woman's embarrassment, concern over what the other person will think, and difficulty bringing it up. Four in five say that women worry the person will leave them, seven in 10 say women don't know enough about these issues or they don't think their partner needs to know, and almost half think these are simply things women should not talk about (See Chart 8).
III. KNOWLEDGE ABOUT HIV/AIDS AND OTHER STDS

Close to one million people in the U.S. are living with HIV/AIDS, ${ }^{6}$ with approximately 40,000 new HIV infections occurring annually. ${ }^{7}$ Today, women represent a third of new HIV infections, ${ }^{7}$ yet four in five women underestimate (or do not know) the number of women affected by HIV/AIDS. Other STDs - like chlamydia, HPV, and herpes - are even more common. The most recent estimates indicate that at least one in four Americans is expected to get an STD (including HI V) in their lifetime ${ }^{1}$ - a fact that only about one in five women recognizes.

STD TRANSMISSION AND SYMPTOMS
For the most part, women are quite knowledgeable when it comes to STDs, particularly understanding the risk of transmission from certain behaviors and the asymptomatic nature of many STDs. Almost all women know that STDs are spread through intercourse and that there are treatments available. Nine in 10 women correctly say that people with STDs may not display symptoms for months or even years after infection. Most know that STDs can be spread even when symptoms are not present - although 15 percent do not. Seven in 10 women understand that it only takes one sexual partner to be at risk.

At the same time, women have certain misperceptions and gaps in their STD knowledge that can jeopardize their health: More than a third are not aware that you can be infected with some STDs without having intercourse, and almost one in five believes that you only have to worry about STDs if you have sex with a lot of people. One in 10 is not aware that STDs can be spread through oral sex, and three in five women do not know that women are more susceptible to STDs. Almost nine in 10 women realize that many people who have an STD don't know it, yet more than two in five also believe that you would simply "know it" if you had an STD. Almost half of the women surveyed also believe that STDs are not a problem if you are "responsible" (See Chart 9).

## CHART 9

## STD TRANSMISSION KNOWLEDGE

## Percentage of women who do not know

| Women are more susceptible to STDs than men | 60\% |
| :---: | :---: |
| You can be infected with some STDs without having intercourse | 35\% |
| It only takes one sexual partner to be at risk | 27\% |
| You only have to worry about STDs if you have a lot of partners | 19\% |
| STDs can be spread even when symptoms are not present | 15\% |
| Many people who have an STD don't know | 13\% |
| STDs can be transmitted through oral sex | 10\% |
| Birth control pills provide no protection against HIV/AIDS | 10\% |
| Birth control pills provide no protection against other STDs | 8\% |
| STDs may not display symptoms for months or years | 7\% |

## CONSEQUENCES OF STDS

Millions of people suffer from the long-term consequences of STDs, which include infertility and pregnancy-related complications as well as a variety of cancers and other chronic diseases. Women are more likely than men to experience long-term health problems due to STDs, and the effects can also be more severe and more frequent among women. For example, once infected, women are more susceptible to reproductive cancers and infertility. In fact, at least 15 percent of all infertile American women have tubal damage caused by pelvic inflammatory disease (PID), an infection that results from certain untreated STDs - primarily chlamydia and gonorrhea; PID can also increase the risk of ectopic pregnancies, which can be life-threatening. Recent studies have found that certain types of HPV cause virtually all cervical cancers worldwide, and Hepatitis B (HBV) infections - two-thirds of which are transmitted sexually - are linked to chronic liver disease, including cir-
rhosis and liver cancer. STDs such as syphilis in pregnant women can seriously harm a developing fetus, and for pregnant women infected with genital herpes, there is a small chance of transmission during childbirth. ${ }^{8}$

Women's knowledge of the long-term consequences of STD infection is mixed. Most are aware of possible pregnancy and birth-related complications and the link between STDs and fertility problems. Fewer are aware that an STD can lead to chronic liver disease, and almost half do not know that having an STD increases a persons' risk of becoming infected with HIV. Two in five are unaware that STDs can cause some kinds of cancers (See Chart 10).

CHART 10

| ---: | ---: |
| becoming infected with HIV/AIDS |

STDs can cause some kinds of cancer $\quad 40 \%$

STDs can cause problems with fertility $\quad 11 \%$

STDs can cause pregnancy and birth related complications

TESTING FOR HIV AND OTHER STDS
More than half of women report having been tested for an STD, although these numbers vary significantly by age - with younger women more likely to have been tested than older women. Two-thirds of women say they have been tested for HIV, with some differences by age. However, misperceptions about how tests are performed may mean that these rates overstate the actual proportion of women who have been tested.

For instance, one in five who say they have been tested for STDs also say they believed that it was a routine part of an exam - an assumption that may not hold true, depending on provider practices. One in six women who say they were tested for HIV may also be mistaken because they, too, were under the impression it was a routine part of the exam. Some women also believe that the Pap test actually
screens for STDs and HIV. To know for sure whether she has been tested, a woman must discuss the issue with her health care provider - which many do not - and give consent for HIV screening.

Women who have not been tested for HV or other STDs cite a variety of reasons, with lack of personal concem topping the list. Two-thirds say they have not been tested because they do not think they are at risk, although younger women are less likely to say this than older women. The next most common reasons are: not knowing what is involved, not knowing where to go, cost, not wanting to know, and not wanting the results to appear in their medical records (See Chart 11).

## CHART 11

## HIV AND STD TESTING

Percentage of women who say they have discussed the following with a health care provider

Percentage of women who report having been tested-and those who may be mistaken

| :--- | :---: |
| Didn't have a <br> discussion/Under the <br> impression it was a <br> routine part of exam |  |

Among women who have not been tested the reasons why

the PAP TEST
Although Pap smears have become a nearly routine part of gynecologic care, there is still a lot of confusion surrounding what the test does and does not do. More than four in five women do know the primary reason a Pap test is performed: to screen for abnormal cells that can indicate precancer or cancer of the cervix. At the same time, however, two in five also believe it is a test for STDs other than HIV/ AIDS - a misunderstanding that may reflect the fact that a few "high-risk" types of one STD (the human papillomavirus, HPV) are now known to cause virtually all cervical cancers. ${ }^{9}$ (The Pap does not test for HPV, but a DNA test can be performed along with it - or as a back-up to an abnormal Pap result - to determine whether a woman is infected with a high-risk HPV type. ${ }^{10}$ ) Finally, almost one in 10 women also believe the Pap smear is a test for HIV/AIDS or pregnancy (See Chart 12).
IV. CONTRACEPTIVE CHOICES AND PRACTICES

When it comes to choosing a method of contraception, pregnancy prevention tends to be the number one factor for most women. More than four in five also say ease of use, how well it protects against HIV/AIDS and other STDs, and their partners' preferences are also important elements in their decision-making. For seven in 10 women, whether it interferes with intimacy is a significant consideration, while not having to discuss it matters to almost three in five. Cost also plays a role for about half of women (See Chart 13).

CHART 13
CONTRACEPTIVE CHOICES
Percentage of women who say the following are important when choosing a method of contraceptive

ATTITUDES ABOUT THE PILL, CONDOMS, AND UNINTENDED PREGNANCY
Birth control pills and condoms are highly effective at preventing pregnancy when used correctly, ${ }^{11}$ a fact that nine in 10 women recognize. However, women seem to feel somewhat more confident about the pregnancy protection afforded by birth control pills than by condoms: Fifty-four percent say that birth control pills are "very effective" at preventing pregnancy, and another 39 percent say they are "somewhat effective." In contrast, 27 percent feel that condoms are "very effective" and another 63 percent say they are "somewhat effective."

When it comes to protecting against STDs, including HIV, about nine in 10 women consider condoms to be effective, and a similar proportion recognize that birth control pills provide no protection against disease. Still, some women do believe that that "the Pill" may prevent HIV/AIDS and other STDs.

While half of the approximately 6.3 million pregnancies occurring in the U.S. each year are unintended, ${ }^{2}$ a third of women think it is far fewer - and a quarter simply don't know. Women also tend to be pretty divided when it comes to considering an unplanned pregnancy something that happens only to people who aren't "responsible." This is true even as nearly two-thirds of sexually active women also say they have experienced a "pregnancy scare" at some point in their lives - thinking they might be pregnant when they did not plan to be.

CONDOM USE
Although almost half of women say it is embarrassing to buy condoms, seven in 10 sexually active women say they have done so. More than a third have condoms in their home, and about one in 10 carry them when they go out. Four in five women agree that a woman - or a man - who carries a condom looks "responsible," but about half also think someone who carries condoms has a lot of sexual partners.

Women feel condoms can be difficult to talk about - and, sometimes, even to use. About a third agree that it is hard to bring up the subject of condoms with a partner, although four in five have suggested using one. Almost three-quarters agree that men generally think using condoms has a negative effect on their sexual experience, and a third of sexually active women have had a partner try to talk them out of using a condom. Almost two in five women say they have been in a situation when they intended to use a condom but did not (See Chart 14).

Single women are more likely to have suggested condom use with a partner, bought condoms, keep them in their homes, and carry them when they go out. They are also more comfortable buying condoms, and are more likely to say they have done so.

## CHART 14

## CONDOM EXPERIENCES

Percentage of sexually active women who report they have done the following

EMERGENCY CONTRACEPTION AWARENESS AND USE
Even with two dedicated emergency contraception (EC) products now on the market, women's awareness and use of this back-up bith control method remains low - particularly compared with other contraceptive options. Roughly two-thirds of women know that there is something a woman can do to prevent pregnancy in the event of contraceptive failure or unprotected sex. However, only about one in 20 women reports ever having used EC, with variations based on both age and relationship status. Younger women, and those who are single, are more likely than their older or married/cohabiting counterparts to have done so (See Chart 15 for comparisons to previous years).

## 2003

67\%

51\%

41\% $1 \%$

Data from 1997 and 2000 are among women ages 18-44. The 2000 data comes from a Vital Signs survey conducted by the Foundation with Lifetime Television and the 1997 data is from the National Survey of Americans on Emergency Contraception.

METHODOLOGY

The Kaiser Family Foundation/SELF National Survey of Women on their Sexual Health is a nationally representative survey of 800 women ages 18 to 49. The survey was designed by staff at the Foundation, SELF, and Princeton Survey Research Associates (PSRA) and conducted by telephone by PSRA between December 10, 2002 and January 19, 2003. The sample was designed to generalize to all women in continental U.S. telephone households. Weighting was used to adjust for the effects of sample design as well to adjust for minor differences between the set of complete interviews and the populations they represent due to survey nonresponse. The demographic weighting parameters come from a special analysis of the March 2002 Current Population Survey. The response rate for this survey was 41 percent.

This analysis focuses on women's attitudes, knowledge and experiences through key life stages - specifically by age and relationship status (single or married or living as married). Two-thirds of 18 - to 49-year-old women surveyed are currently married or living with a partner ( $56 \%$ married; $10 \%$ living with a partner). A third are considered "single," including 20 percent who have never been married, 10 percent who are divorced, 2 percent separated, and 1 percent widowed. Ninety-four percent of the women surveyed had ever had sexual intercourse, and 84 percent were currently in a sexual relationship. About half (52\%) of single women interviewed are currently in a sexual relationship.

The margin of error for the total sample of women is plus or minus 3.6 percent. See Table 1 for detailed information on the sampling errors for the report as well as the toplines (See Appendix).
